

Public 311 data alone cannot answer SLA timing questions.

This working prototype uses clearly labeled synthetic records to show the decision workflow.

The buyer problem: public 311 exports can show creation date, status, ward, request type, division, and section, but Toronto's current public file does not expose target or closure timestamps. An honest SLA workflow must join authorized internal work-order fields before it can calculate timing outcomes.

The useful result: an adapter-ready calculation engine that normalizes enriched timestamps, applies configurable response rules, computes margins, and creates a review queue. The bundled proof uses synthetic inputs so its behavior is reproducible without implying official municipal results.

SR-311-001 - Pothole Repair

COMPLIANT

Ward: Ward 10 - Spadina-Fort York Created: 2026-08-01T09:00:00+00:00 Target SLA: 5 days (2026-08-06T09:00:00+00:00)

Closed: 2026-08-04T14:30:00+00:00 Duration: 3.23 days Margin: 1.77 days

Reason Code: CLOSED_BEFORE_SLA_TARGET | Lifecycle: CLOSED_ON_TIME

Source context: City of Toronto 311 public schema and Open Government Licence - Toronto. The displayed IDs, categories, SLA rules, target dates, closure dates, and outcomes are synthetic. Zero personal data is used.

Missing public timing fields require an explicit adapter boundary.

The creative obstacle: prove the workflow without inventing official municipal SLA results.

The technical challenge: the official Toronto 2026 export includes creation date and current status, but not target or closure timestamps. Treating absent fields as evidence would create false breach or compliance claims.

The implemented correction: separate the licensed public schema from a synthetic, adapter-ready SLA contract. The proof exercises ISO8601 parsing, configurable hypothetical targets, explicit **INCOMPLETE_DATA_REVIEW** routing, and machine-readable fixture labels. Production use would require authorized internal target and closure fields.

Actual code excerpt: explicit fixture label and failure route

```
created_dt = parse_iso_timestamp(raw_created)
if created_dt is None:
    return review("INVALID_CREATED_TIMESTAMP", sla_target_days)

parsed_raw_target = parse_iso_timestamp(raw_target)

if raw_target not in (None, "") and parsed_raw_target is None:
    return review("INVALID_TARGET_TIMESTAMP", sla_target_days)

if parsed_raw_target is not None and rules == DEFAULT_CATEGORY_SLA_DAYS:
    target_dt = parsed_raw_target
    target_derived = False
else:
    target_dt = datetime.fromtimestamp(created_dt.timestamp() + (sla_target_days * 86400))
    target_derived = (parsed_raw_target is None)
```

Contrasting Rule Scenario: Reducing the hypothetical Pothole Repair target from 5 days to 3 days re-classifies synthetic request SR-311-001 (completed in 3.23 days) from **COMPLIANT** to **SLA_BREACHED**.

Synthetic Ward Scenario Ranking

Ward 10 - Spadina-Fort York | Total: 5 | Eval: 4 | Compliant: 3 | Breached: 1 | Compliance: 75.0%

Ward 14 - Toronto-Danforth | Total: 5 | Eval: 5 | Compliant: 3 | Breached: 1 | Compliance: 60.0%

Ward 01 - Etobicoke North | Total: 5 | Eval: 5 | Compliant: 2 | Breached: 3 | Compliance: 40.0% (BOTTLENECK)

Try it locally or in the web workbench in about one minute:

1. Open the public web demo link below (no login required).
2. Click 'Evaluate SLA Engine' to run default 5/3/10/2 day SLA rules.
3. Click 'Apply Strict Rules (3/2/5/1)' and observe request status re-classifications.
4. Export evaluated JSON / CSV queues with explicit audit reason codes.
